Diffusion of B	Botnets			

We study the phenomeon because it is **largely widespread** and **highly lucrative**.

Diffusion of Botnets

We study the phenomeon because it is **largely widespread** and **highly lucrative**.

Three examples:

Flashback: year 2012, 600K compromised Macs, credentials stealing

- Grum: from 2008 to 2012, **840K** compromised devices, **40bln/mo** spam emails
- TDL-4: from 2011, **4,5M** victims in the first 3 months, known as *"indestructible"*.

Cinala Daint	f Eailura			

Single Point of Failure

If bots cannot communicate with their master, they are **innocuous** and **do no produce profit**.

The C&C channel is single point of failure of the whole botnet.

Security **defenders strive to disable C&C channels** as means to disable botnets without sanitizing the infected machines.

Classification of Previously-unseen Domains I

We leverage the fingerprints to **classify previously-unseen domain**, so to extend the blacklist we employed during the bootstrap.

Introduction State of the Art System Description System Evaluation Conclusions

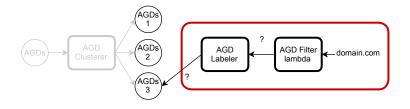

Classification of Previously-unseen Domains II

Given a previously-unseen domain, we answer the questions:

Introduction State of the Art System Description System Evaluation Conclusions

Classification of Previously-unseen Domains II

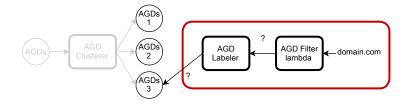

Given a previously-unseen domain, we answer the questions:

• does it look like it was **automatically generated** (with loose threshold)?

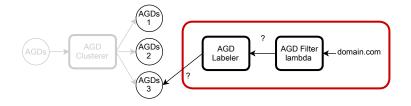

Given a previously-unseen domain, we answer the questions:

- does it look like it was **automatically generated** (with loose threshold)?
- 2 can we associate it with one of the known domain families?

Given a previously-unseen domain, we answer the questions:

- does it look like it was **automatically generated** (with loose threshold)?
- 2 can we associate it with one of the known domain families?

If yes, then we found a new malicious AGD.

For instance, no information is available about the membership of a given malicious domain to one family of AGDs

Approach to Validation

Validating Phoenix is far from trivial, as it **produces novel knowledge**.

For instance, no information is available about the membership of a given malicious domain to one family of AGDs

In lack of an established ground truth, we:

- run quantitative tests to validate each module,
- provide a qualitative validation of the whole approach.

Introduction 0000000000000000	State of the Art	System Description	System Evaluation ○0●000000000	Conclusions
AGD Filter E	valuation: I	Dataset		

We employ AGDs of **known botnets of the past** to verify the accuracy of the filter.

AGD Filter Evaluation: Dataset

We employ AGDs of **known botnets of the past** to verify the accuracy of the filter.

Specifically, we use the AGDs of:

- Conficker.A (7,500),
- Conficker.B (7,750),
- Conficker.C (1,101,500),
- Torpig (420),
- Bamital (36,346).

AGD Clustering Evaluation

Stefano Zanero

Introduction State of the Art System Description System Evaluation Conclusions

AGD Clustering Evaluation

We show that the clustering based on DNS features **partitions** well the AGDs according to **DGA-dependent features** (e.g., TLD, domain length).

AGD Clustering Evaluation

We show that the clustering based on DNS features partitions well the AGDs according to DGA-dependent features (e.g., TLD, domain length).

We verify the correspondence between the families we isolate and some active botnets: Conficker, Bamital, SpyEye, Palevo.

AGD Clustering Evaluation

We show that the clustering based on DNS features **partitions** well the AGDs according to **DGA-dependent features** (e.g., TLD, domain length).

We verify the correspondence between the families we isolate and some active botnets: **Conficker**, **Bamital**, **SpyEye**, **Palevo**.

Moreover, we verify the sensitivity of the clustering from the configuration thresholds, and we evaluate them automatically.

 - $\clubsuit \rightarrow \heartsuit \rightarrow \diamondsuit \rightarrow \diamond \rightarrow .$ com

Phoenix **may not provide warnings earlier** than similar systems employing NXDOMAIN replies:

- it is fed with data that take longer to be collected,
- nevertheless, this makes our system **easier to deploy** and more **privacy-preserving**.

- it identifies previously-unseen malicious domains and associates them to the activity of a specific botnet;

Conclusions

Phoenix gives the following contributions:

- it identifies groups of AGDs between malicious domains and characterizes the generation processes under more realistic hypoteses with respect to similar approaches;
- it identifies previously-unseen malicious domains and associates them to the activity of a specific botnet;
- it produces novel knowledge, which allows—for instance—to track the evolution of a botnet over time.
